

Data stored in a relational database and *not* in a spreadsheet.

Foreign Keys identify records in a different table.

Primary Keys identify each record in a table.

Spreadsheets can be used to store data, but they do pose some problems because data is often duplicated and lacks rules to keep it valid.

Relational databases use tables to separate data by kind and use identifiers called keys to show the relationships between data.

By adding this structure, the data is more likely to be valid.

Inserting and deleting data
Author and book records can be inserted independently (as long as keys only point to data that actually exists).

Updating data
Since an author only has one record in the database, changing the value of a field is very simple.
